Subject: Provide a way to embed decisions within expressions

From: Van Snyder

Reference: 03-258r1, section 2.8.1

1 Number

2 TBD

3 Title

4 Provide a way to embed decisions within expressions.

5 Submitted By

6 J3

au Status

8 For consideration.

Basic Functionality

- 10 Provide a way to embed decisions within expressions. For example, a distfix IF-THEN-ELSE operator
- 11 would be useful.

2 Rationale

- 13 One sometimes needs to select one thing or another to be used within an expression. At present, one
- 14 creates a temporary variable, sets that variable with an if-then-else or where-elsewhere construct, then
- 15 evaluates the expression using that variable.
- 16 Another use is to compute whether an actual argument is present. This cannot be done by creating a
- 17 temporary variable. Instead, one uses an if-then-else construct with the argument textually present in
- one branch but not the other. If one wants to compute whether n actual arguments are present, one
- needs a complicated if-then-elseif-else construct with 2^n branches.
- 20 Other languages include a distfix if-then-else operator. For example, in C one can write p ? x : y, which
- 21 is pronounced if p then x else y. If such an expression were to be the target in a pointer assignment, its
- 22 result should be a target, not a value. This spelling could work in Fortran as well. Clunky alternatives
- 23 might be .IF. p .THEN. x .ELSE. y .ENDIF., or more briefly p .THEN. x .ELSE. y. For the case
- of computing whether an actual argument is present, the syntax might be p? x, pronounced if p then
- 25 x is the actual argument, else the actual argument is not present. p shall be scalar in this case.
- 26 The difference for these operators as compared to existing operators is that only the first operand (p in
- 27 the example) is initially evaluated. Then the second operand (x in the example) is evaluated if (where in
- 28 the elemental case) p is true, else (elsewhere in the elemental case) the third operand (y in the example)
- 29 is evaluated if it appears. The first operand is required to be logical, while the others are required to be
- 30 of the same type, type parameters and rank. If p is an array, x and y have to be the same shape as p.
- 31 In the p ? x case, p would necessarily have to be a scalar. The result type, type parameters and rank
- 32 are those of x. If p is a scalar, the shape of the result is x or y depending on whether p is true or fales.
- 33 If p is an array, the shape of the result is the shape of p.
- 34 It would introduce substantial complication into the defined-operator discussion to allow to overload this
- operator. Fortunately, it seems unlikely that would be useful.
- 36 The functionality almost exists in the MERGE intrinsic function. The reason it isn't quite the same
- 37 as what is described here is that the standard specifies that all arguments of a function are evaluated

31 January 2004 J3/04-192r1

1 before the function is invoked. Also, we don't have a two-argument MERGE that causes its result not

2 to exist (for purposes of argument association) if its first argument is false.

3 Estimated Impact

4 Minor.

5 Detailed Specification

- 6 Provide a way to embed a decision witin an expression, for example, a distfix IF-THEN-ELSE operator.
- 7 Provide a way to compute whether an actual argument is present.
